Observing features may incur a cost

- Time, Money, Risk
- Medical diagnosis
- Internet applications

We need to classify test examples on a budget.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

- Goal: Supervized Learning with:
 - budget B > 0
 - feature costs $C: [i, \ldots, n] \rightarrow \mathbb{R}^+$
 - Limited by budget at test time
- We call such a learner feature-efficient

Related Work

- Feature-efficient prediction by randomly sampling from a full ensemble

Reyzin ('11)

- 1 Run AdaBoost to produce an ensemble predictor
- 2 Sample from ensemble randomly until budget is reached

3 Take unweighted average vote of samples

There's a simpler alternative:

Stop boosting early!

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Modify AdaBoost to stop training early when budget runs out. The resulting predictor will be feature-efficient. Modify base learner selection when costs are non-uniform.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Algorithm: AdaBoost

AdaBoost (S) where: $S \subset X imes \{-1,+1\}$

1: given:
$$(x_1, y_1), ..., (x_m, y_m) \in S$$

2: initialize $D(i) = 1$

2: initialize
$$D_1(I) = \frac{1}{m}$$

3: for
$$t = 1, ..., T$$
 do

4: train base learner using distribution D_t .

5: get
$$h_t \in \mathcal{H} : X \to \{-1, +1\}.$$

- 6: choose $\alpha_t = \frac{1}{2} \ln \frac{1+\gamma_t}{1-\gamma_t}$, where $\gamma_t = \sum_i D_t(i) y_i h_t(x_i)$.
- 7: update $D_{t+1}(i) = D_t(i) \exp(\alpha_t y_i h_t(x_i))/Z_t$,
- 8: end for
- 9: output the final classifier $H(x) = \operatorname{sign}\left(\sum_{t=1}^{T} \alpha_t h_t(x)\right)$

Algorithm: AdaBoost with Budgeted Training

AdaBoostBT(S,B,C) where: $S \subset X \times \{-1,+1\}$, B > 0, $C : [n] \rightarrow \mathbb{R}^+$

- 1: given: $(x_1, y_1), ..., (x_m, y_m) \in S$
- 2: initialize $D_1(i) = \frac{1}{m}, B_1 = B$
- 3: for t = 1, ..., T do
- 4: train base learner using distribution D_t .
- 5: get $h_t \in \mathcal{H} : X \to \{-1, +1\}$.
- 6: **if** the total cost of the unpaid features of h_t exceeds B_t **then**
- 7: set T = t 1 and end for
- 8: **else** set B_{t+1} as B_t minus the total cost of the unpaid features of h_t , marking them as paid
- 9: choose $\alpha_t = \frac{1}{2} \ln \frac{1+\gamma_t}{1-\gamma_t}$, where $\gamma_t = \sum_i D_t(i) y_i h_t(x_i)$.
- 10: update $D_{t+1}(i) = D_t(i) \exp(\alpha_t y_i h_t(x_i))/Z_t$,
- 11: end for
- 12: output the final classifier $H(x) = \operatorname{sign}\left(\sum_{t=1}^{T} \alpha_t h_t(x)\right)$

Optimizing for Non-Uniform Costs

AdaBoost normally choses a base learner that maximizes γ_t (i.e. minimizes error rate)

- What about non-uniform costs?
- How should cost influence base learner selection?

Training error of AdaBoost is bounded by [Freund & Schapire '97]

$$\hat{\mathsf{Pr}}[\mathsf{H}(x) \neq y] \leq \prod_{t=1}^{T} \sqrt{1 - \gamma_t^2}$$

- Driven down by both high γ_t s and high T (ie low costs)
- To estimate *T* we may make an assumption
- If in round t we choose hypothesis h_t, assume we can find base learners with same c on future rounds.

Minimize training error bound

minimize
$$\prod_{t=1}^{T} \sqrt{1-\gamma_t^2}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

If all $\gamma_i = \gamma_t(h)$

minimize
$$(1 - \gamma_t(h)^2)^{\frac{T}{2}}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

$$T = \frac{B}{c(h)}$$
 by assumption

minimize
$$(1 - \gamma_t(h)^2)^{\frac{B}{2c(h)}}$$

(ロ)、(型)、(E)、(E)、 E) の(の)

$\frac{B}{2}$ can be removed from exponent

minimize
$$(1 - \gamma_t(h)^2)^{\frac{1}{c(h)}}$$

• We may now choose a base learner satisfying

$$h_t = \operatorname{argmin}_{h \in \mathcal{H}} \left((1 - \gamma_t(h)^2)^{\frac{1}{c(h)}} \right)$$
(1)

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Tradeoff Contours

- Alternate estimate of T based on milder assumption
- If in round *t* we choose hypothesis *h*_t, assume we can find base learners with *c* equal to the average base learner cost.
- Average cost of base learners is $\frac{(B-B_t)+c}{t}$
- Choose a base learner satisfying

$$h_t = \operatorname{argmin}_{h \in \mathcal{H}} \left(\left(1 - \gamma_t(h)^2 \right)^{\frac{1}{(B - B_t) + c(h)}} \right)$$
(2)

Average cost should produce a smoother optimization

Experimental Results: $C \sim Unif(0,2)$

Compare to Decision Trees

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへで

- Budgeted training improves significantly on AdaBoostRS
- Modifying with optimizations 1 and 2 tend to yield additional improvements
- With non-uniform costs:
 - Optimization 1 tends to win for small budgets
 - Optimization 2 tends to win for larger budgets

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

- Too many cheap features can kill optimization 1 (ionosphere, sonar, heart, ecoli)
- Optimization 2 avoids this trap, since cost becomes less important as $t \to \infty$
- Both optimizations 1 and 2 run higher risk of over-fitting than AdaBoostBT

- Improve optimization for cost distributions with few cheap features
- Consider adversarial cost models
- Boost using weak learners other than decision stumps (e.g. decision trees)
- Extend our ideas to confidence-rated predictions [Schapire & Singer '99]
- Refine optimizations by considering the complexity term in AdaBoost's generalization error bound
- Study making other machine learning algorithms feature-efficient through budgeted training
